## LINEAR EQUATIONS

**Linear:** each variable appears only to the first power, not multiplied by another variable.

- YES:  $3x+6y-4z=9$ ,  $7(x_1+6x_2)=9(x_3-x_2)$  (distributes to linear)
- NO:  $2x^2+4x-7=y$  (squared),  $(3x_1-x_2)(5x_3-x_4)=9$  (product of variables)

**Solution counts** — equation vs variable count tells you almost NOTHING:

- Same #eq as #var: could be 0, 1, or  $\infty$  (NOT guaranteed 1)
  - Fewer eq than var: either 0 or  $\infty$  (no unique solution possible)
  - More eq than var: could be 0, 1, or  $\infty$  (NOT guaranteed no solution)
  - Homogeneous ( $RHS=0$ ): always  $\geq 1$  solution; fewer eq than var  $\rightarrow$  guaranteed  $\infty$
- 

## AUGMENTED MATRICES & EROs

**Build  $[A|b]$ :** coefficients in variable order; missing variable  $\rightarrow$  0 entry.

**Valid EROs:** (1) swap rows, (2) multiply row by  $c \neq 0$ , (3)  $cR_j + R_i \rightarrow R_i$

- INVALID: multiply by 0; replace  $R_i$  with combo not involving  $R_i$ ; two ops simultaneously

**RREF reading:**

- Row  $[0 \ 0 \ \dots \ 0 \ | \ c]$  with  $c \neq 0 \rightarrow$  NO solution
  - All columns pivot, no  $0=0$  rows  $\rightarrow$  UNIQUE solution
  - Free column(s) + no contradiction  $\rightarrow$  INFINITELY MANY (set free vars =  $s_1, s_2, \dots$ )
- 

## VECTORS & SUBSPACES

**3-condition subspace test** (all three must hold):

1. Contains zero vector
2. Closed under addition
3. Closed under scalar multiplication (including NEGATIVE scalars!)

**Classic failures:**

- Inequality constraint ( $a \leq b$ ): fails condition 3 (multiply by -1)
- Non-homogeneous constraint ( $b_1=1$ ): fails condition 1 (zero vector has  $b_1=0$ )
- Homogeneous linear constraint ( $b_3=b_1+b_2, b_1=0, f(2)=0$ ): always a subspace

**Zero vector in abstract spaces:** in P4, zero = the polynomial 0 (not a column vector)

**Parametric form:**  $x = p + s_1d_1 + s_2d_2$  (particular + free params  $\times$  direction vectors) Direction vectors have 1 in the free-variable row, 0 in all other free-variable rows.

---

## INDEPENDENCE, SPAN, BASIS

**Dependent iff** nontrivial combo = 0; one vector is combo of others.

### Quick dependence tests (no row reduction):

- Zero vector in set  $\rightarrow$  dependent
- Two vectors scalar multiples  $\rightarrow$  dependent
- More vectors than dimension of space  $\rightarrow$  dependent ( $>n$  vectors in  $R^n$ : always dependent)

### Subset/superset rules:

- Subset of independent = independent
- Superset of dependent = dependent

**Span:**  $b \in \text{span}\{v_1, \dots, v_k\}$  iff  $[v_1 | \dots | v_k | b]$  is consistent.

**Basis = independent + spans.** Exactly  $n$  vectors in any basis for  $R^n$ .

**For  $n$  vectors in  $R^n$ :** independent  $\leftrightarrow$  spans  $\leftrightarrow$  basis (any one implies all three)

**Pivot column method:** row reduce B

- Rank = # pivots =  $\dim(\text{span of columns})$
- No free columns  $\rightarrow$  independent | Pivots in every row  $\rightarrow$  spans  $R^m$

**Representation:** Rep\_B(v): solve  $[b_1 | b_2 | \dots | v] \rightarrow$  coordinates w.r.t. basis B.

---

## FUNDAMENTAL SUBSPACES (for $m \times n$ matrix A)

Subspace	Definition	Lives in	How to compute
$\text{col}(A)$	span of columns	$R^m$	Pivot cols of ORIGINAL A
$\text{row}(A)$	span of rows	$R^n$	Nonzero rows of RREF
$\text{null}(A)$	solutions to $Ax=0$	$R^n$	Solve $Ax=0$ , take direction vectors

**Which space does a vector belong to?**

- Built as combo of COLUMNS of A  $\rightarrow$   $\text{col}(A)$
- Built as combo of ROWS of A  $\rightarrow$   $\text{row}(A)$
- Satisfies  $Ax=0 \rightarrow \text{null}(A)$

**Rank-nullity:** rank + nullity = #COLUMNS (not rows!)

- rank =  $\dim(\text{col}) = \dim(\text{row})$
- nullity = #cols - rank =  $\dim(\text{null})$

**Worked examples:**

- $5 \times 7$  matrix,  $\dim(\text{row})=2$ :  $\dim(\text{col})=2$ , nullity =  $7-2=5$  (NOT 3)
  - $9 \times 11$  matrix, nullity = 7: rank =  $11-7=4$ ,  $\dim(\text{row})=4$
  - $5 \times 7$  matrix, 2 zero rows in RREF: rank = 3, nullity =  $7-3=4$
- 

## LINEAR TRANSFORMATIONS T: $R^n \rightarrow R^m$

**Matrix:**  $m \times n$  ( $m$  rows = codomain dim,  $n$  cols = domain dim) **Linearity:**  $T(au+bv) = aT(u)+bT(v) \rightarrow T$  of combo = combo of T's outputs **T(0)=0 always.** If  $T(0) \neq 0$ , function is not linear. **Domain:**  $R^n$  (inputs) | **Codomain:**  $R^m$  (outputs) **Standard matrix:**  $A = [T(e_1) | T(e_2) | \dots | T(e_n)]$  ( $j$ -th column =  $T(j\text{-th std basis vector})$ )

**Computing T of a linear combination:** If  $v = c_1u_1 + c_2u_2$ , then  $T(v) = c_1T(u_1) + c_2T(u_2)$  — no matrix needed.

**Exam example:**  $T([0,1,-9,8])=[1,-5]$ ,  $T([9,1,0,-2])=[5,-9]$   $[54,11,-45,28] = 5[0,1,-9,8]+6[9,1,0,-2] \rightarrow T = 5[1,-5]+6[5,-9] = [35,-79]$

**Kernel** =  $\text{null}(A)$  (subspace of domain) | **Image** =  $\text{col}(A)$  (subspace of codomain)

**Derivative as linear transformation:**

- $d/dx: P_3 \rightarrow P_2$  (reduces degree by 1)
  - $d^2/dx^2: P_3 \rightarrow P_1$  (reduces degree by 2; image is  $P_1$ , not  $P_2$ )
- 

## TRANSFORMATION ARITHMETIC & ERO MATRICES

**Arithmetic:**  $(aS+bT)(v) = aS(v)+bT(v)$  Exam:  $(-4S+3T)([0,1,-4,9]) = -4[3,1]+3[-6,4] = [-12,-4]+[-18,12] = [-30,8]$

**ERO matrices** (left-multiply to perform ERO):

ERO	Matrix form	Key entry
$R_i \leftrightarrow R_j$	Identity with rows $i,j$ swapped	—
$cR_i \rightarrow R_i$	Identity with $(i,i) = c$	On diagonal
$cR_j + R_i \rightarrow R_i$	Identity with $(i,j) = c$	Row=destination, Col=source

**ERO matrix examples:**

- $[0 \ 0 \ 1; \ 0 \ 1 \ 0; \ 1 \ 0 \ 0] \rightarrow R_1 \leftrightarrow R_3$  (rows 1 and 3 of I are swapped)
- $[1 \ 0 \ 0; \ 0 \ 1 \ 4; \ 0 \ 0 \ 1] \rightarrow 4R_3+R_2 \rightarrow R_2$  (4 in position (2,3): row 2 = dest, col 3 = source)
- TRAP:  $c$  in  $(i,j)$  means " $cR_j + R_i \rightarrow R_i$ " — row of  $c$  is modified row, col of  $c$  is source row

**Invertible transformation T (all equivalent):**

- $\text{RREF}(A) = I \mid \text{rank}(A) = n \mid \text{null}(A) = \{0\} \mid \det(A) \neq 0$

**Invertibility rules:**

- $T(v) = w \leftrightarrow T^{-1}(w) = v$  (bidirectional)
- $T(T^{-1}(v)) = v$  and  $T^{-1}(T(v)) = v$  (always)
- If  $T^{-1}(w) = v$ , then  $T(v) = w$  ← most useful inference direction
